# Agenda

- 802.11 QoS Building Blocks
- Legacy QoS:  
The Enhanced Distributed  
Channel Access (EDCA) Model
- How QoS Works in Wi-Fi6/6E
- AireOS Wireless LAN QoS  
Deployments
- IOS-XE / Catalyst 9800 QoS  
Deployments
- Next-Gen QoS: IEEE 802.11be  
and beyond

# 802.11 QoS Building Blocks

# Comparing Wired and Wireless QoS

- Wired environments are Full Duplex, Wireless is Half Duplex (for now)
  - Half duplex environments are very susceptible to collisions
- Thus, wired QoS is mostly concerned with managing packet loss due to congestion problems (solved with queuing, etc.)

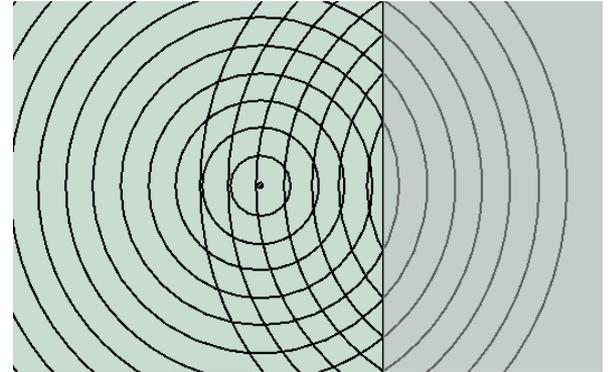

Wireless QoS is focused on a much bigger problem:

1. WLAN QoS is mostly concerned with reducing the **probability** of a collision for high-priority traffic, based on it's QoS classification
2. Managing congestion is a secondary concern

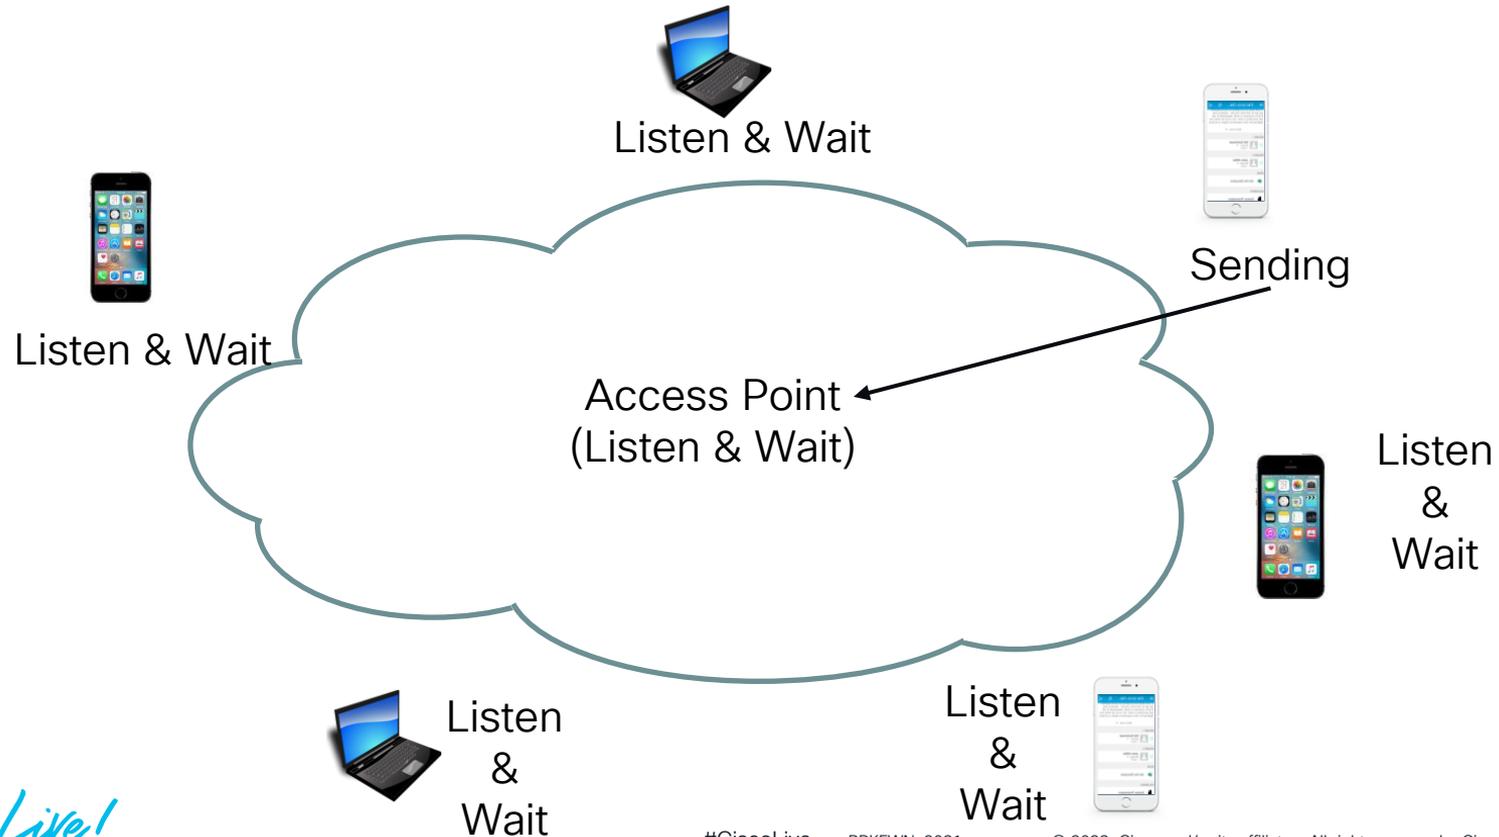

# Carrier Sense Multiple Access / Collision Avoidance

- Wired Hubs use CSMA/CD (collision detection)
  - A station must listen to the medium to see if it is idle before sending it's frame. When it seems idle, it sends the frame.
  - After sending, it listens to see if a collision has occurred
- 802.11 networks use CSMA/CA (collision avoidance)
  - Wireless networks have no way to detect that a collision even occurred!
  - Uses a system of fixed and random wait timers to ensure everyone gets a chance to send
  - Every frame must be acknowledged

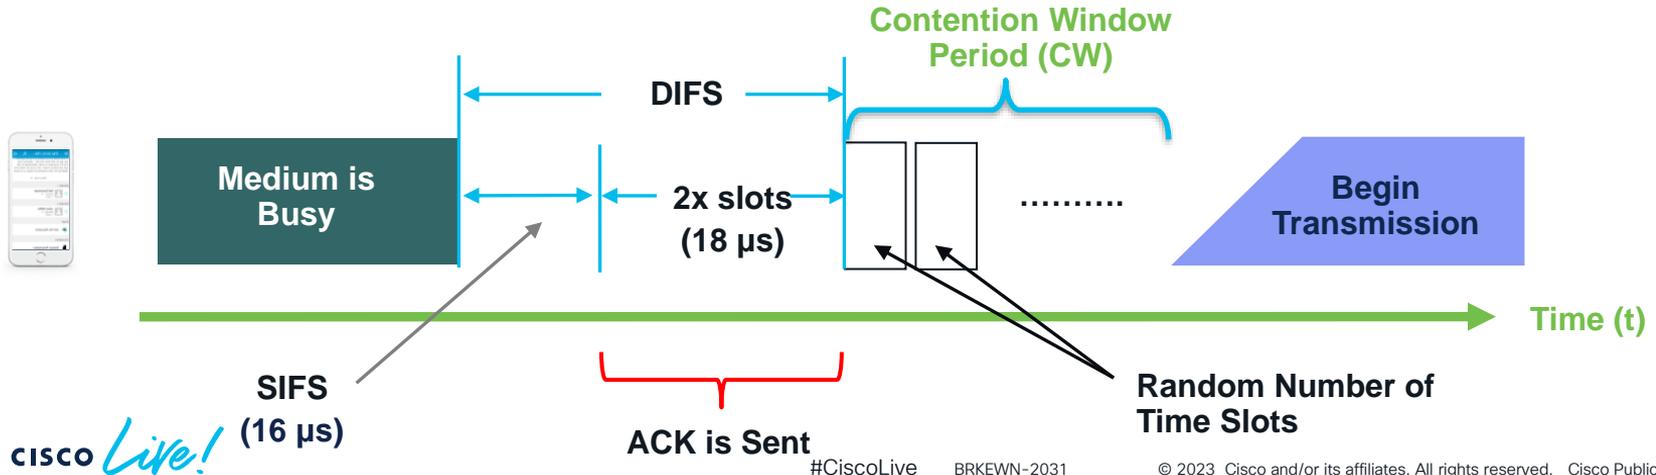

# Wi-Fi Media Access is Contention-Based

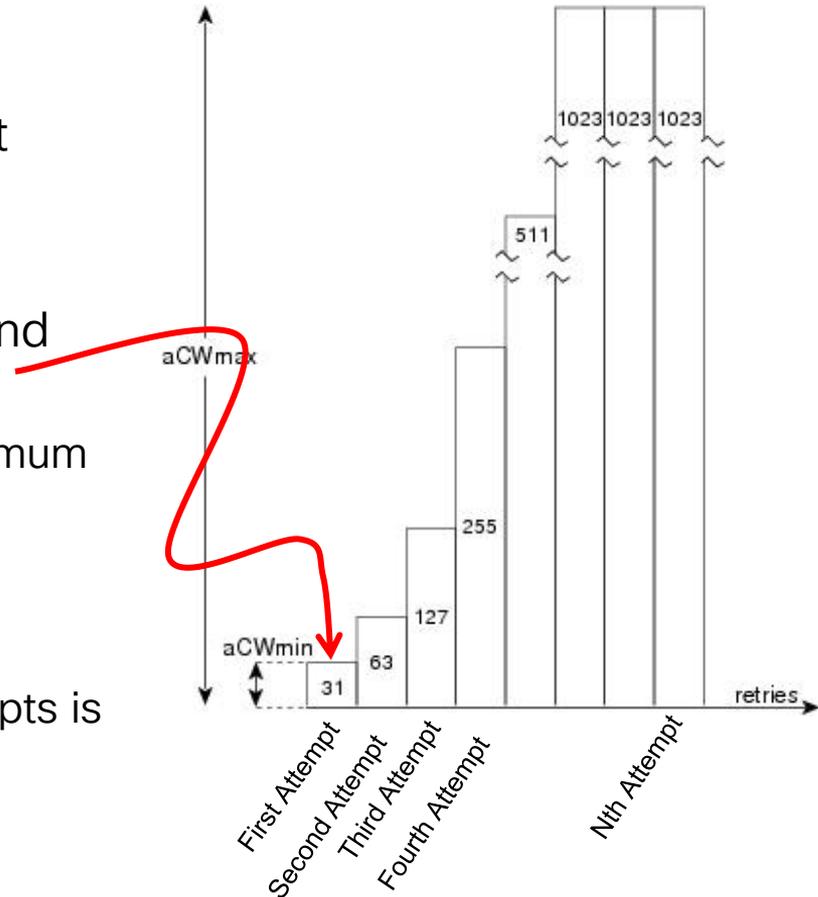

# Distributed Coordination Function (DCF)

- When ready to transmit, all stations must first wait the DCF Interframe space (DIFS)
  - Allows all stations to sense end of frame Tx and allow ACK to be sent back
- Once DIFS has counted down to zero, a random backoff countdown timer (the Contention Window) is generated if the medium is not free.
  - Initially, this value is between zero and a value known as  $CW_{min}$
  - Once the CW counts down to zero, the frame is transmitted

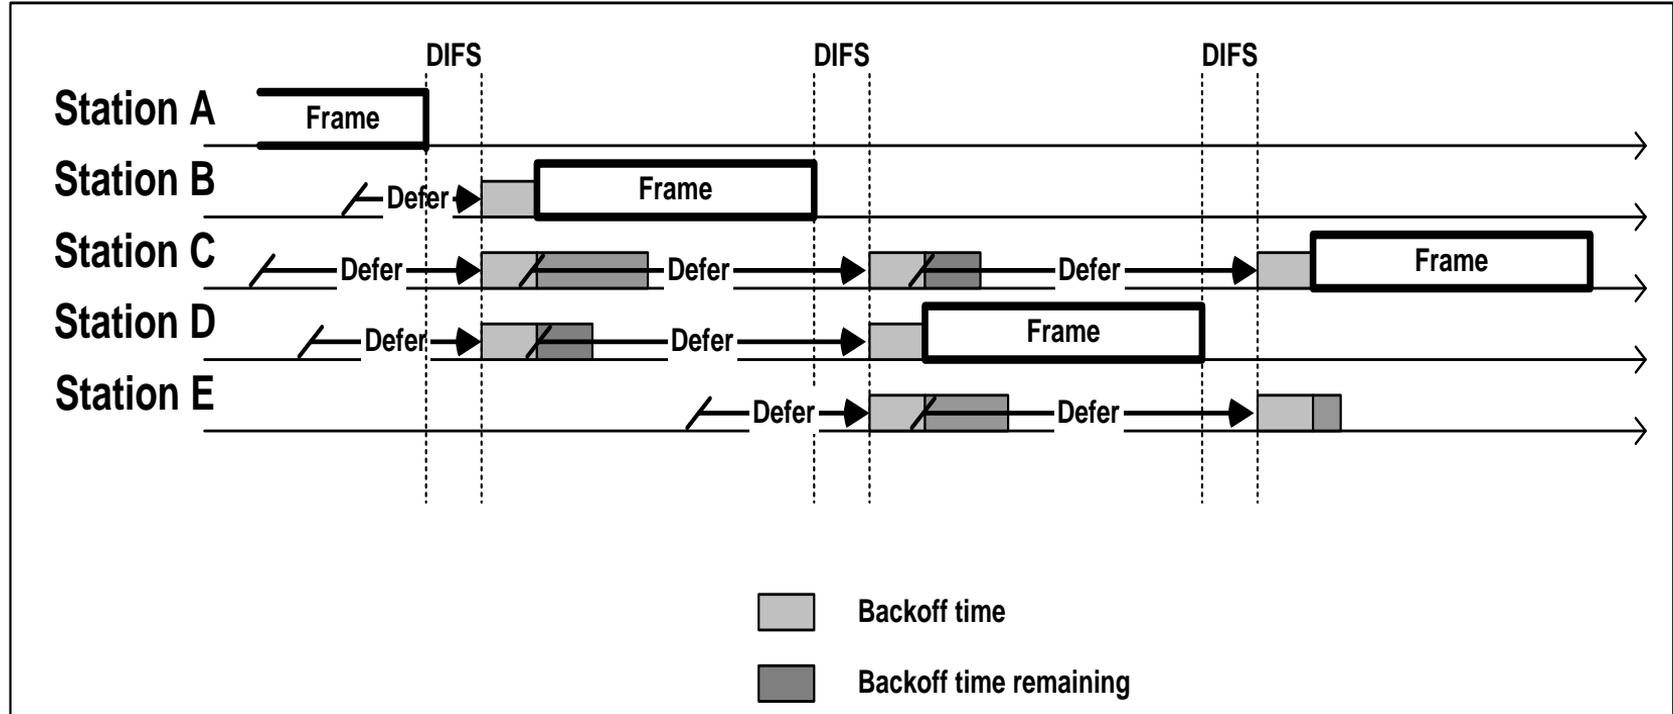

# What if Your Frame Doesn't Get Ack'd?

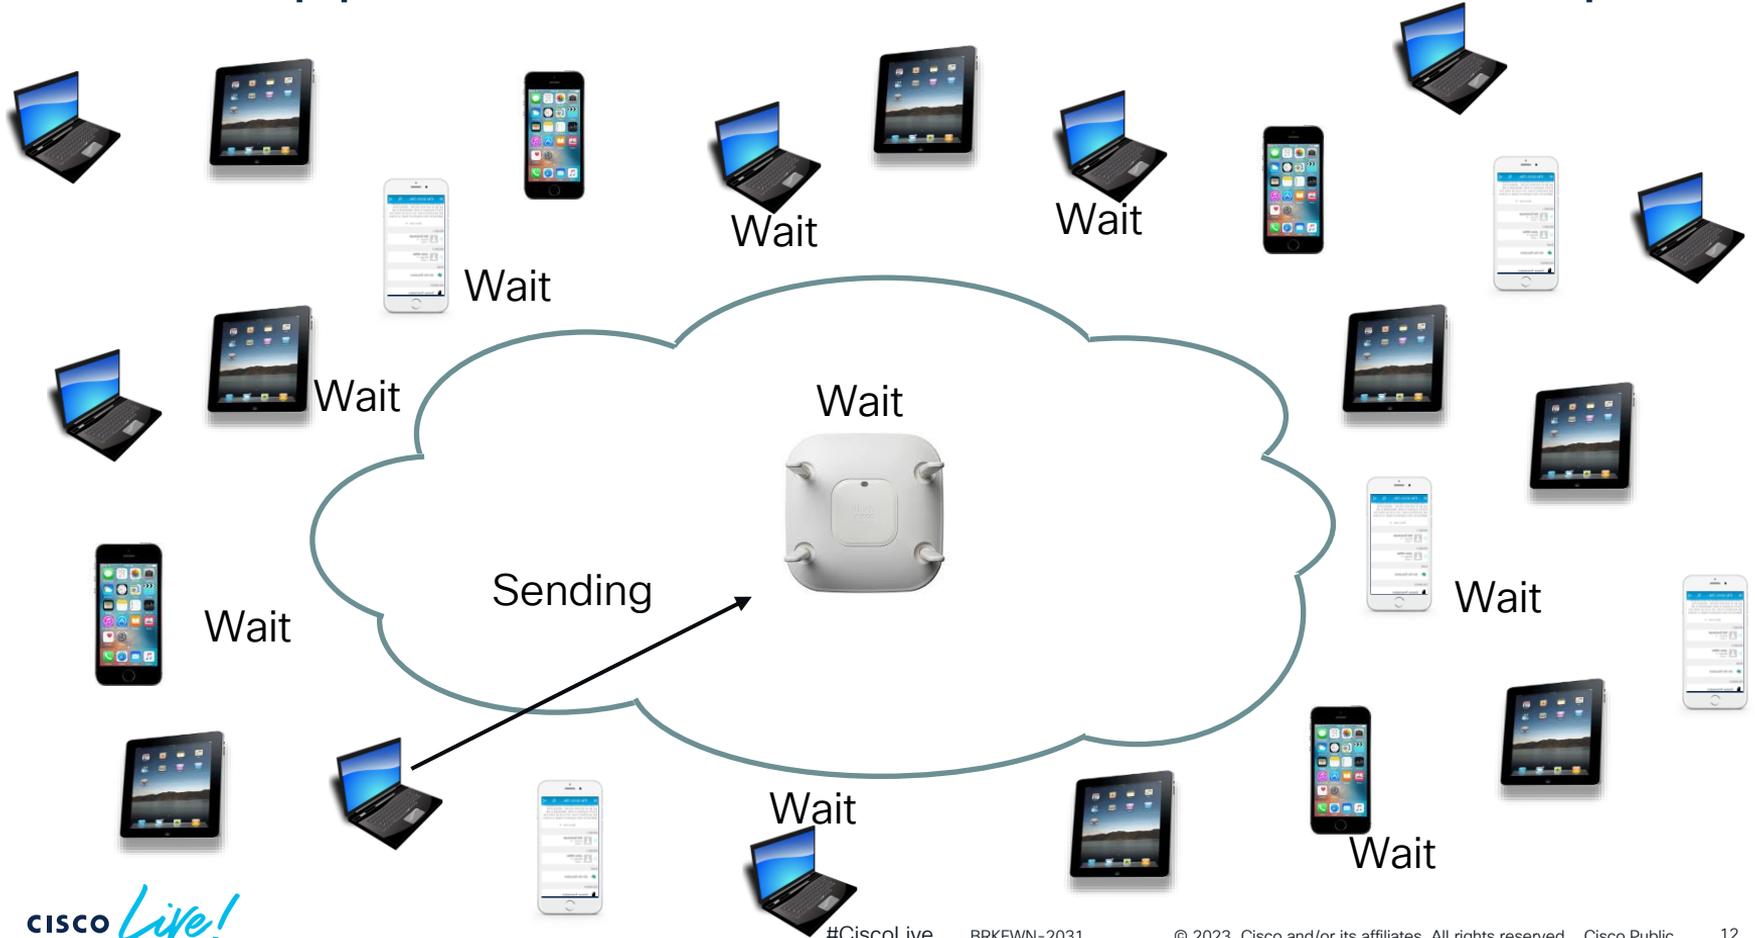

- How do you know the transmission got through okay? The receiving station must send an acknowledgment.
- If the first attempt didn't work (no ACK received), double the previous CW size and pick a new random number.
  - Keep doing this until the CW reaches a maximum size of 1023 slot times.
- How many times should the station keep trying?
  - In Cisco APs, the maximum number of attempts is 64 before the frame is discarded.

# Simplified Example - DCF In Action:

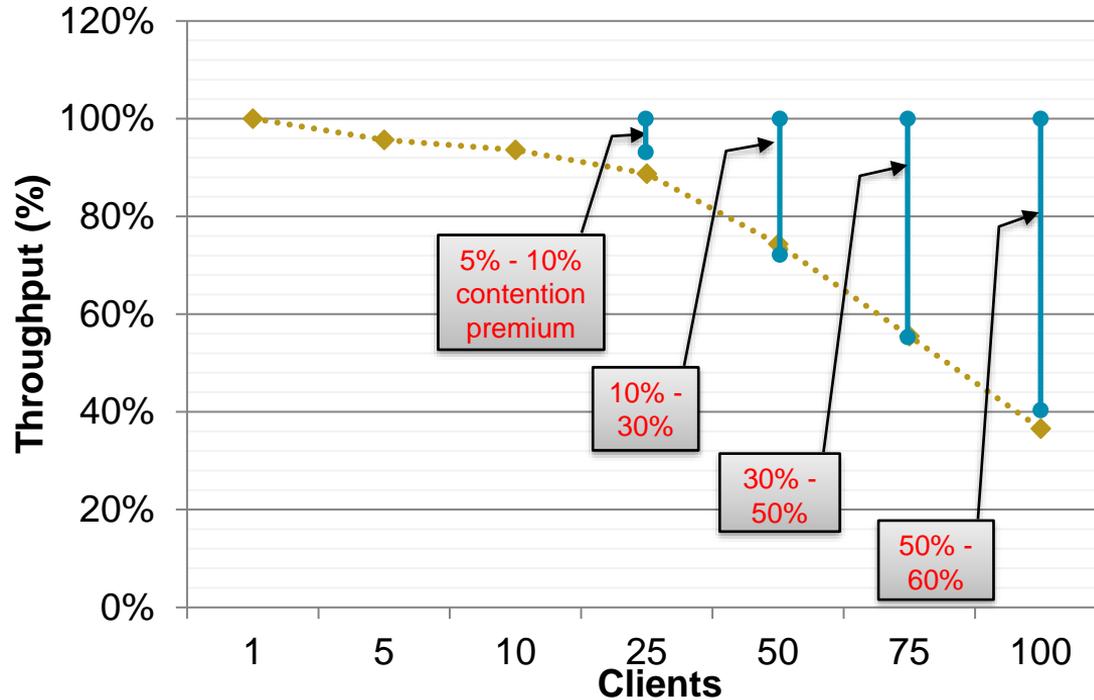

# What Happens When the Client Count Goes Up?

# The Contention Breaking Point (802.11ac)

(source: IEEE 802.11-15/0351r2)

As more clients associate and transmit, WLAN contention increases for all clients, degrading performance for all

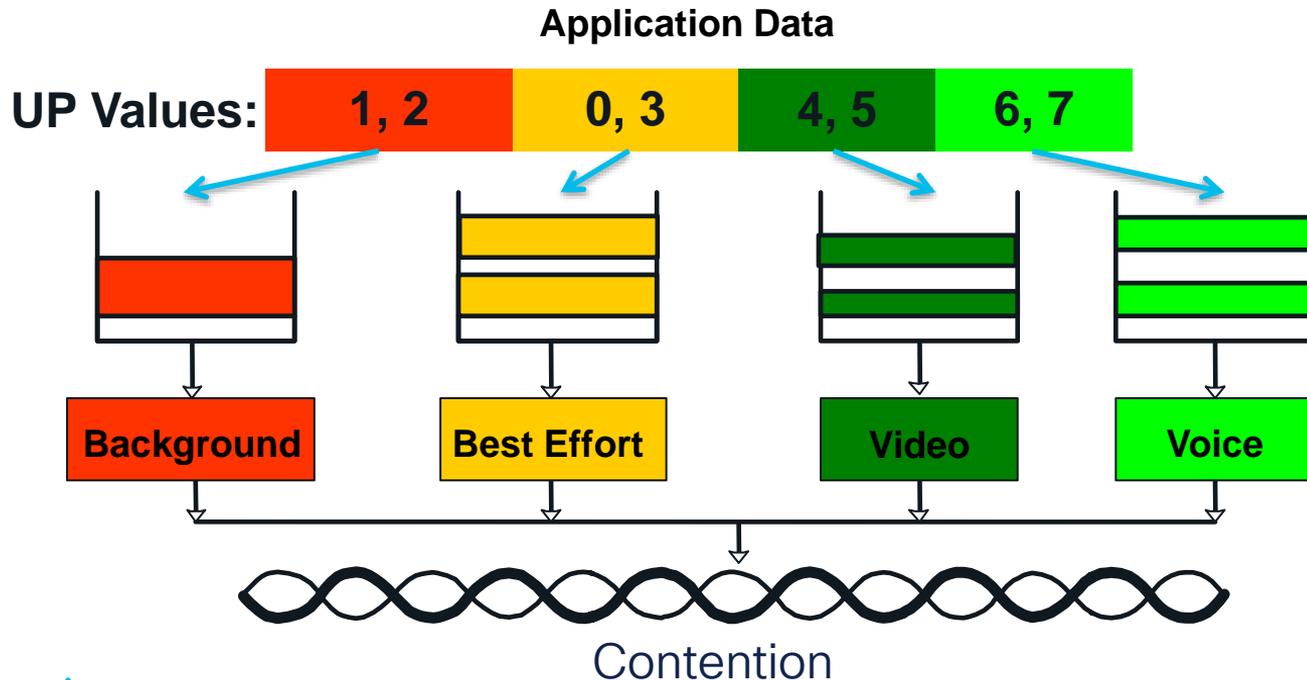

# Legacy QoS: The Enhanced Distributed Channel Access (EDCA) Model

# 802.11e Introduced the Enhanced Distributed Channel Access (EDCA) Model in 2005

- 802.11e was tasked with bringing QoS to Wi-Fi
- EDCA was introduced by IEEE 802.11e in 2005, and has been adopted by the Wi-Fi Alliance as Wireless Multimedia (WMM)
- WMM is now a mandatory part of modern Wi-Fi
  - 802.11a/b/g are based on DCF (no QoS)
  - 802.11n/ac are based on EDCA (QoS is supported)
- Continual improvements, including the 802.11-2016 “rollup”

# #1 Access Categories (ACs)

When wireless frames are transmitted, a 3-bit QoS value known as the **User Priority (UP)** is written into the 802.11 header

# Default DSCP ↔ UP Mapping Table

Traffic Type	DSCP	802.11e UP / WMM	Access Category
Voice	46 (EF)	6	Voice
Interactive Video	34 (AF41)	5	Video
Call Signaling	24 (CS3)	3	Best Effort
Transactional / Interactive Data	18 (AF21)	3	Best Effort
Bulk Data	10 (AF11)	2	Background
Best Effort	0 (BE)	0	Best Effort

# RFC 8325

## Mapping DiffServ to IEEE 802.11

- Reconciles RFC 4594 with IEEE 802.11
- Summarizes our internal consensus on DSCP-to-UP mapping
- Advocates DSCP-trust in the upstream direction (vs. UP-to-DSCP mapping)

### Mapping Diffserv to IEEE 802.11

#### Abstract

As Internet traffic is increasingly sourced from and destined to wireless endpoints, it is crucial that Quality of Service (QoS) be aligned between wired and wireless networks; however, this is not always the case by default. This document specifies a set of mappings from Differentiated Services Code Point (DSCP) to IEEE 802.11 User Priority (UP) to reconcile the marking recommendations offered by the IETF and the IEEE so as to maintain consistent QoS treatment between wired and IEEE 802.11 wireless networks.

#### Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in [Section 2 of RFC 7841](#).

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <https://www.rfc-editor.org/info/rfc8325>.

## #2 Assign Backoff Timers for the Access Category

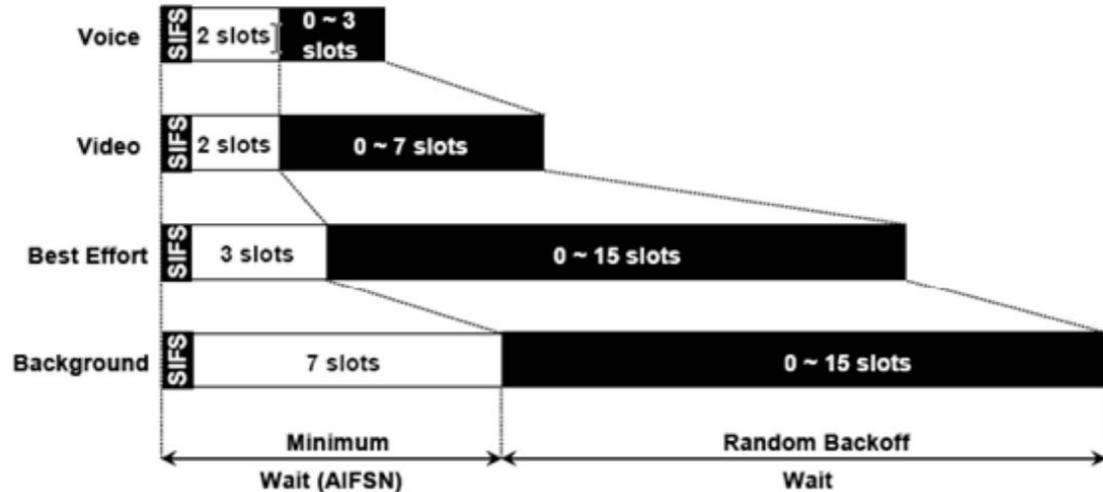

- EDCA manages the ACs in the following way:
  - Variable Arbitration Interframe Spacing (AIFS)
  - Variable  $CW_{min}$  and  $CW_{max}$  values depending on traffic type
  - Values shown are “slot times” –  $9\mu s$  per slot in 802.11

EDCA / WMM AC	AIFS Number	CWmin	CWmax
Legacy DCF	DIFS > 2	15*	1023
Voice	2	3	7
Video	2	7	15
Best Effort	3	15	1023
Background	7	15	1023

\*For 802.11a/g, 802.11b uses 31

# Understanding the Effect of EDCA Timers

- By combining these timers, the theoretical probability of higher priority frames getting serviced first is greatly improved (but is not guaranteed in every case)
- Simply having a queue doesn't give you QoS – how you manage the queue is what matters.

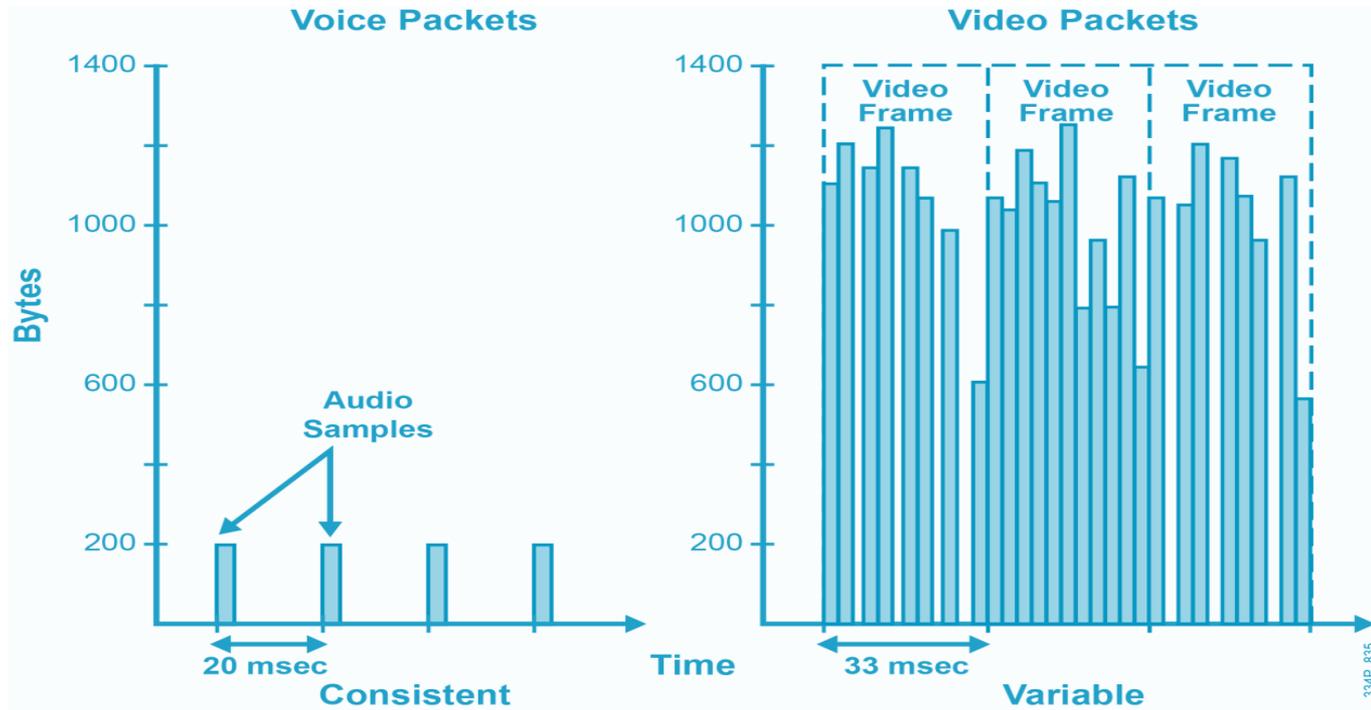

# #3 Transmission Opportunity (TXOP)

- TXOP is a timer – a station keeps sending until it's TXOP timer counts down to zero
- DCF had no such thing – send one frame and then start again!
- Why is video smaller than the other TXOPs?

EDCA / WMM AC	TXOP ( $\mu$ s)	TXOP (Units)
Voice	2080	65
Video	4096	128
Best Effort	2528	79
Background	2528	79

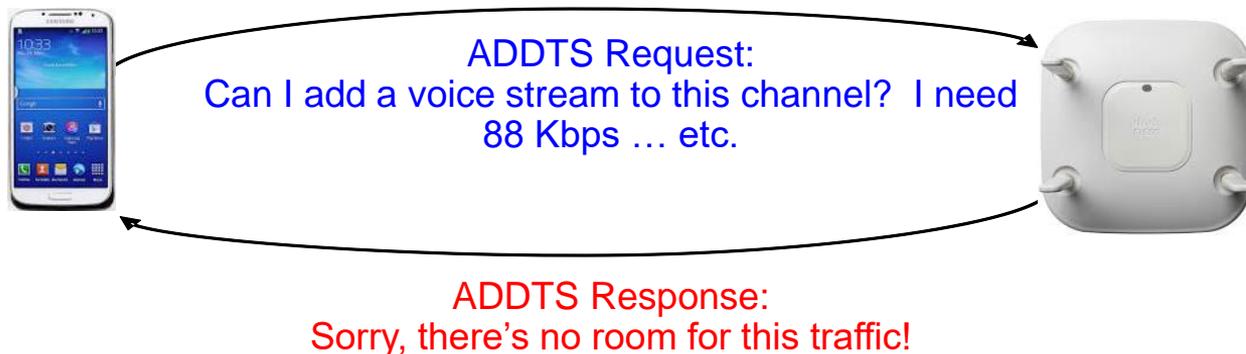

# Real Time Voice vs. Real Time Video Traffic Profile

## Traffic Profile Helps Model TXOP Timers

## #4 Transmission Specification (TSpec)

- TSpec is basically Call Admission Control – management of the number of voice and video traffic flows per AP radio
- Client signals to AP to request it's traffic stream be added to AP (ADDTS)
- TSpec includes data rate, packet size, number of stream & more

# Summary: Four Key 802.11e QoS Enhancements

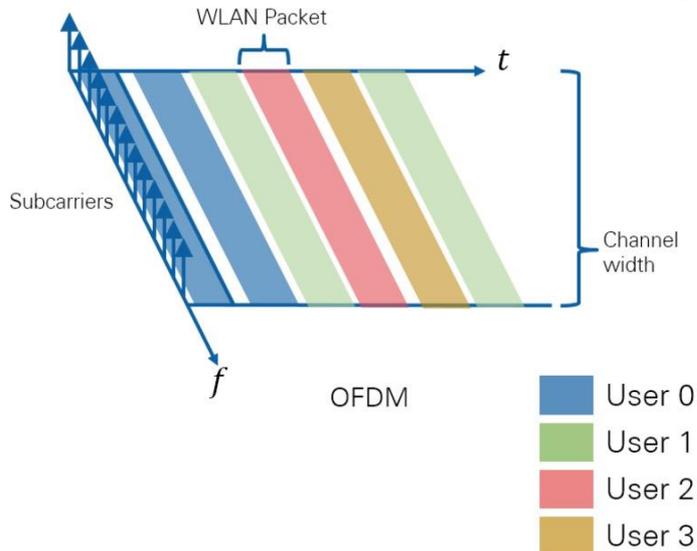

## Enhanced Distributed Channel Access (EDCA):

1. Establishment of four Access Categories and 3-bit User Priority QoS field
2. New timers replacing legacy static DIFS and CW
3. Each AC get's its own Transmission Opportunity (TXOP)
4. Call Admission Control (CAC) with TSpec

# How QoS Works in Wi-Fi6 / 6E (802.11ax)

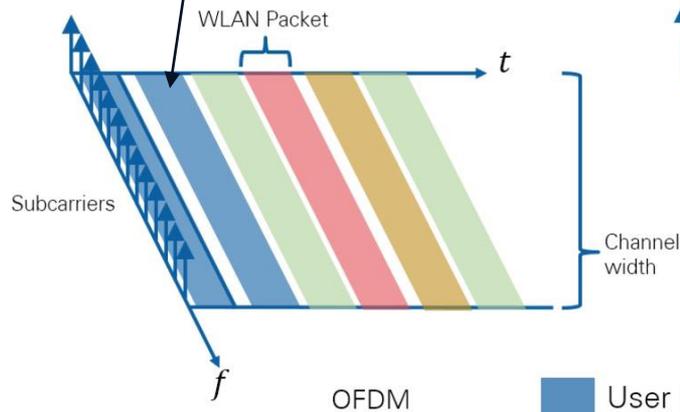

# OFDMA (Orthogonal Frequency Division Multiple Access)

- Subcarriers (Resource Units – RUs) can be assigned to different users for uplink transmissions
  - Can be combined with UL MU MIMO

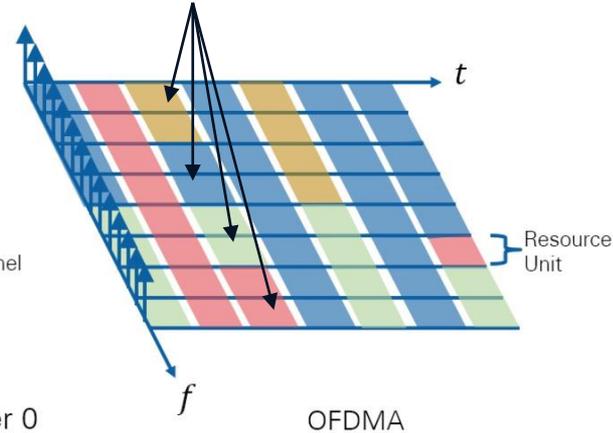

# OFDMA (Orthogonal Frequency Division Multiple Access)

A Single Station Transmits in a Timeslot won by the contention algorithm (EDCA)

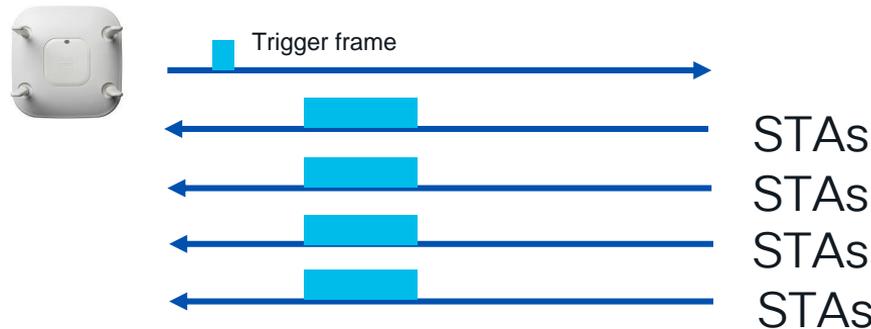

Multiple Stations Transmit in a scheduled Timeslot

- User 0
- User 1
- User 2
- User 3

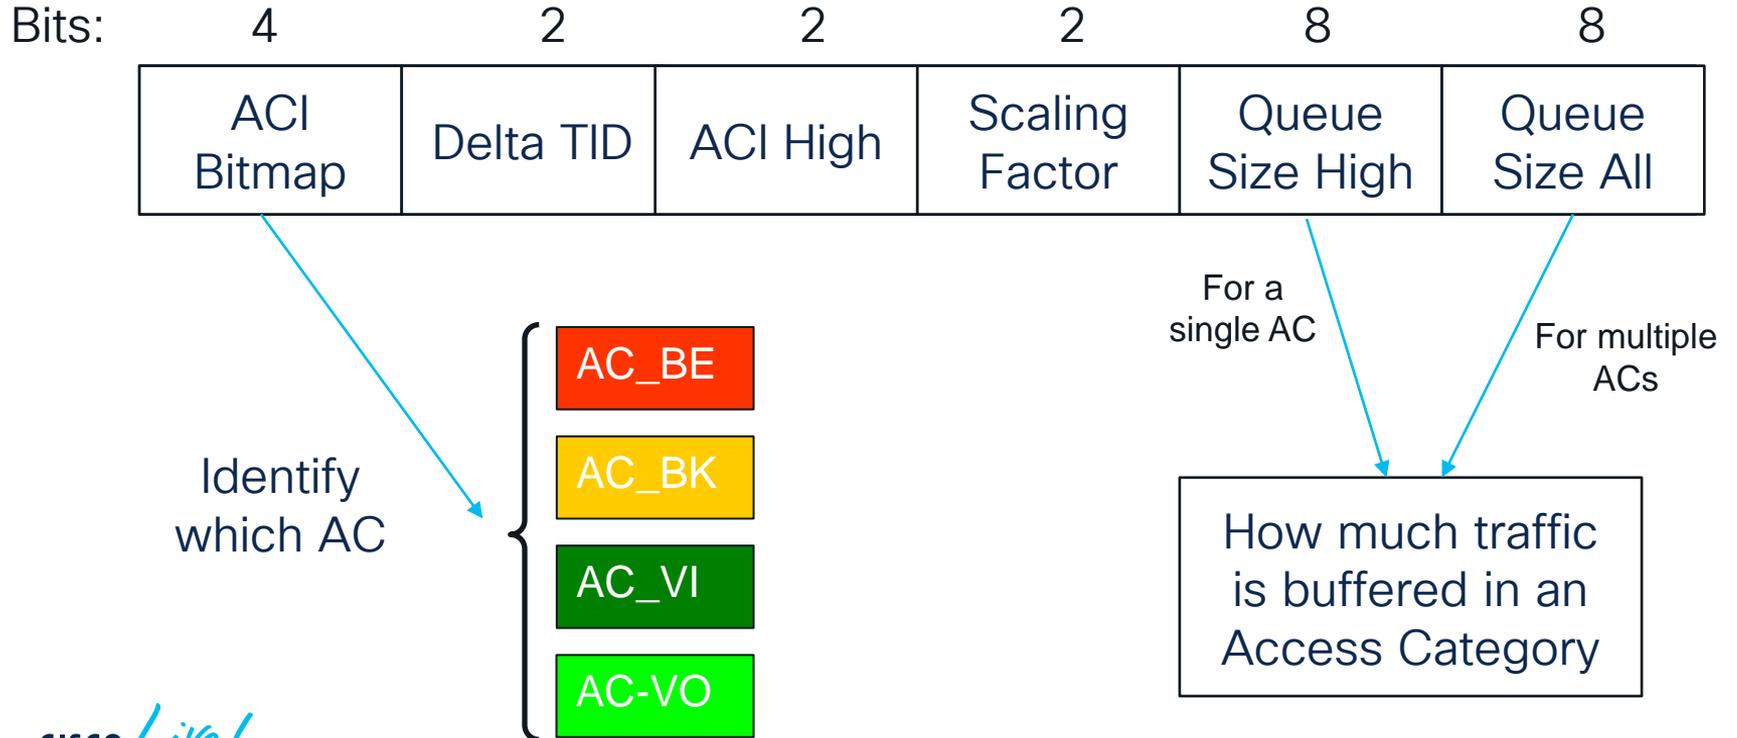

# 802.11ax Uplink (UL) MU-MIMO

- 802.11ac allows for downlink MU-MIMO
- 802.11ax adds uplink MU-MIMO
  - AP checks which STAs can send together
  - AP sends trigger frame and STAs respond all at the same time

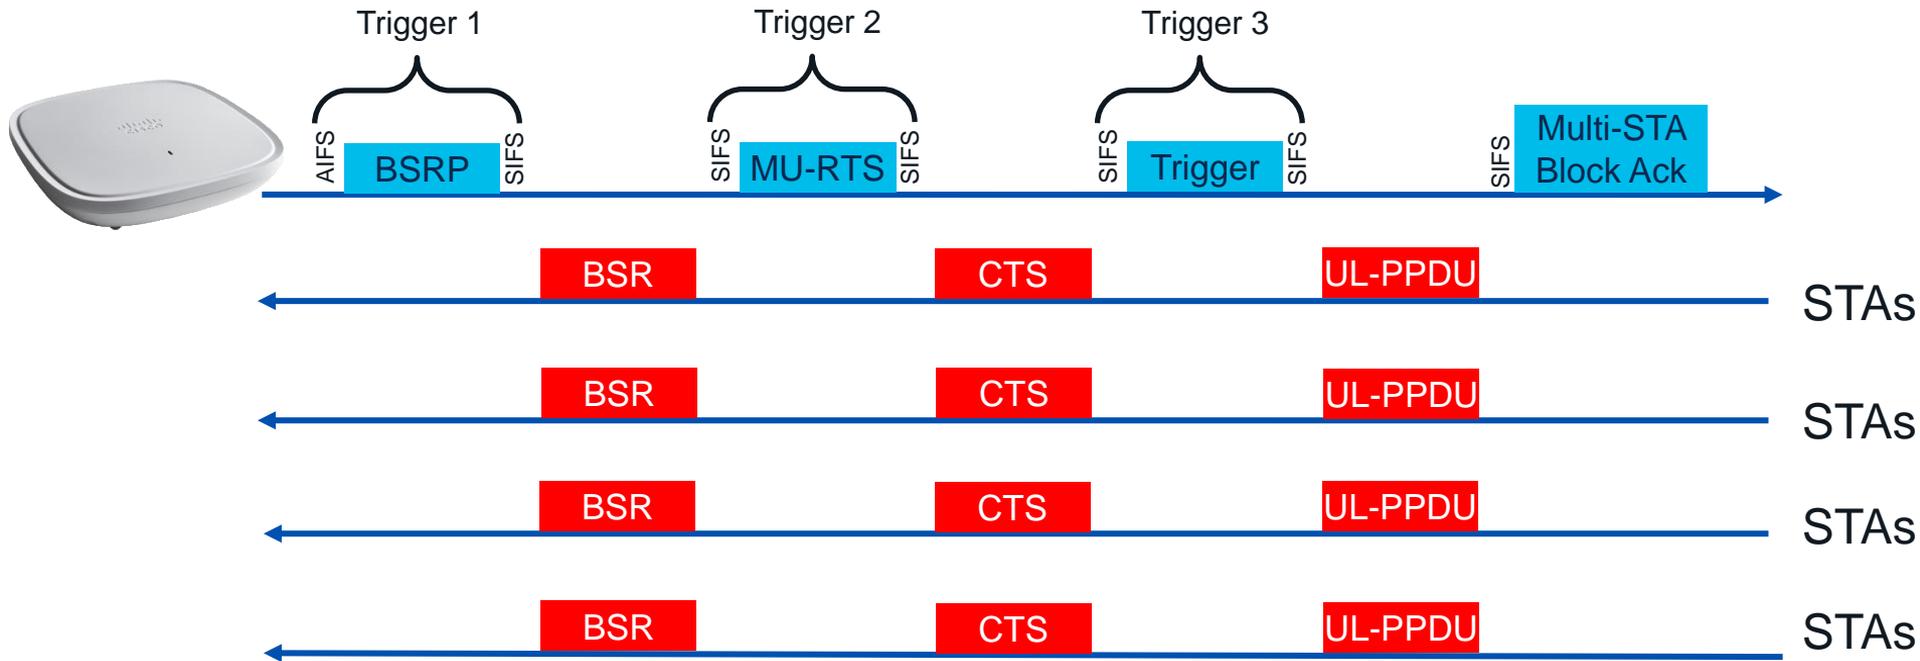

# Buffer Status Reports (BSRs)

STAs may send QoS information in the **BSR Control** subfield of any frame

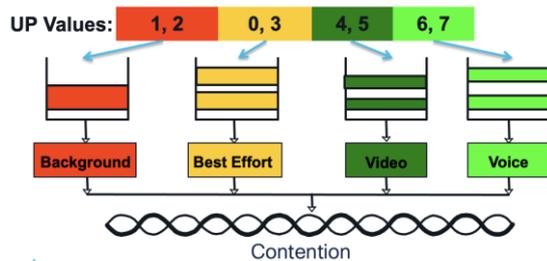

# Buffer Status Report Polling (BSRP)

(Figuring out how many RUs to Assign)

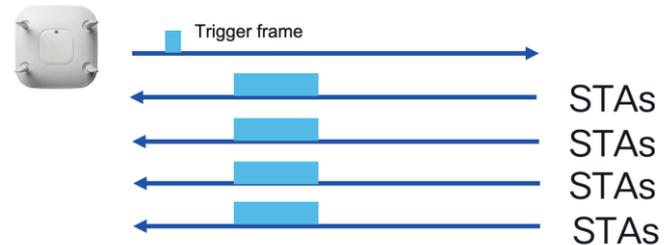

# How Does This Work in Mixed Environments?

- 6GE spectrum is safe – only 11ax clients can work in this spectrum!
- In the lower bands, the AP will need to contend with legacy clients to win the EDCA algorithm so it can perform OFDMA / Multi-User Uplink
  - Over time, as legacy clients go away the medium will shift to a predominant OFDMA model (good)

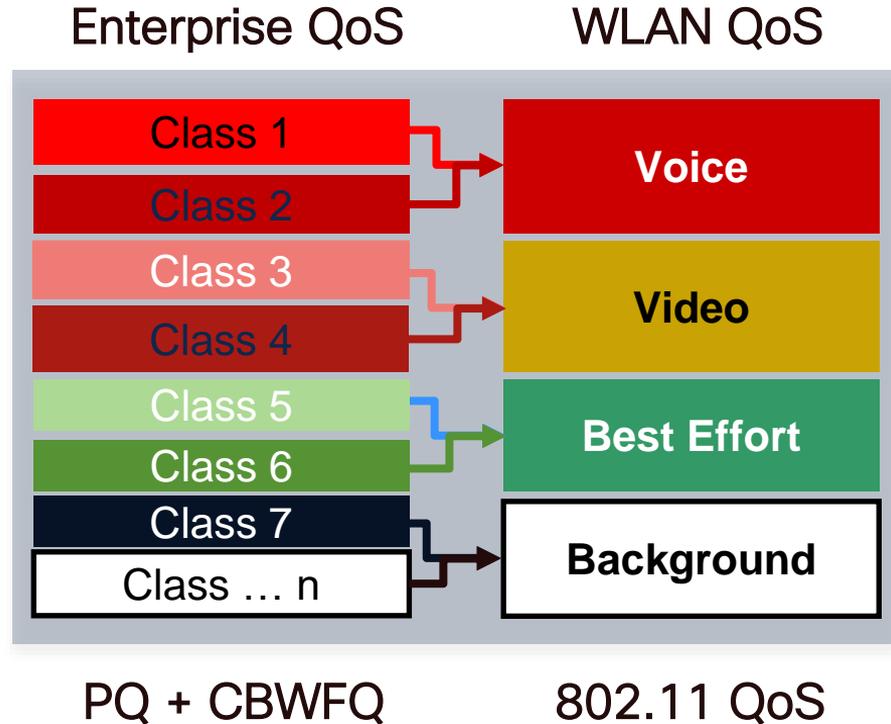

Vs.

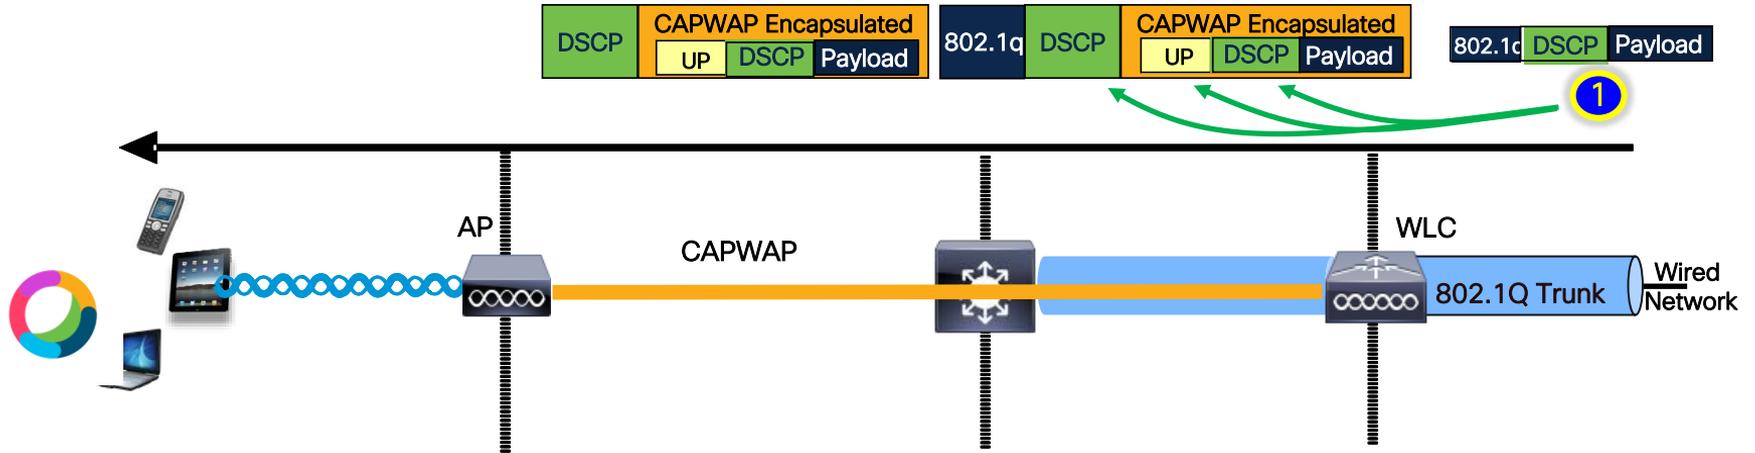

# IOS-XE / Catalyst 9800 QoS Deployment

# A Consistent QoS Strategy: Unifying Wired and Wireless QoS

- By definition of IEEE 802.11e standard there are only 4 levels of service (Access Categories)
- The class-based QoS model should align with the four AC model in the wireless network
- Need to make sure the QoS markings are consistent end-to-end through the network and the design is consistent

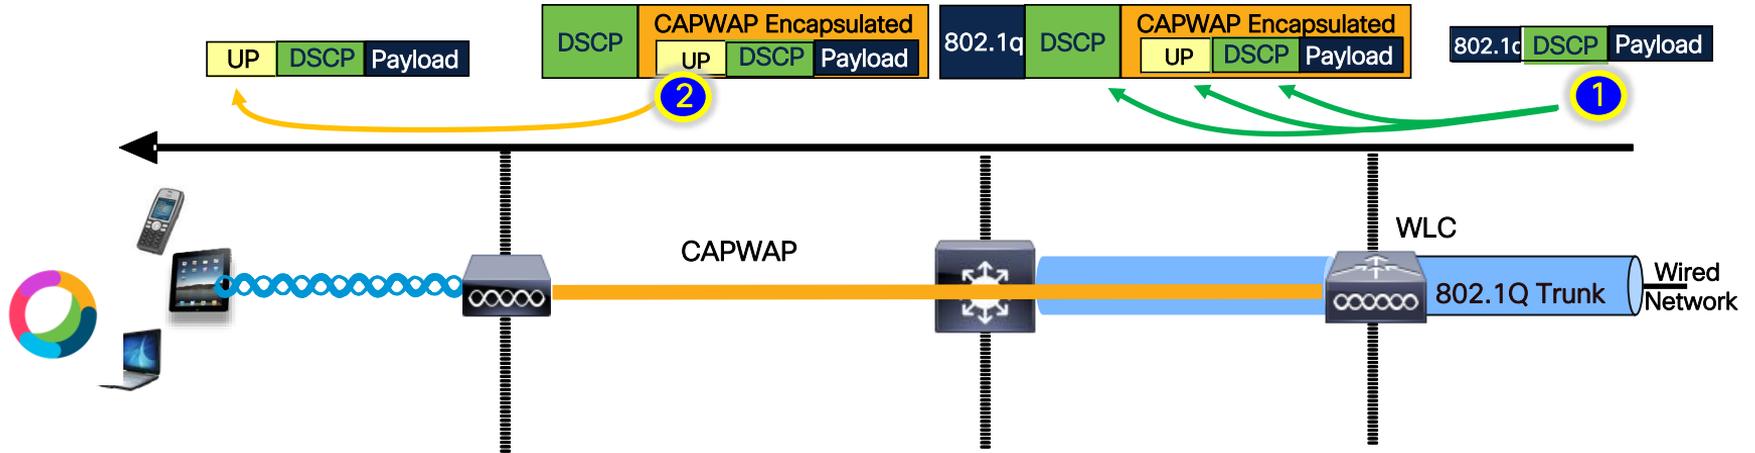

# Catalyst 9800 Downstream QoS Model

- 1 The client packet is received over an 802.1q trunk by the WLC. The WLC uses the DSCP value of the original IP packet and maps it to the outer DSCP of the CAPWAP tunnel (assuming no ceiling value is applied via Metal QoS at the WLC). It also maps DSCP to UP and set it in the inner 802.11e header

**Note:** class of Service (CoS) tagging is not supported in 9800 (supported but not recommended in AireOS)

# Catalyst 9800 Downstream QoS Model

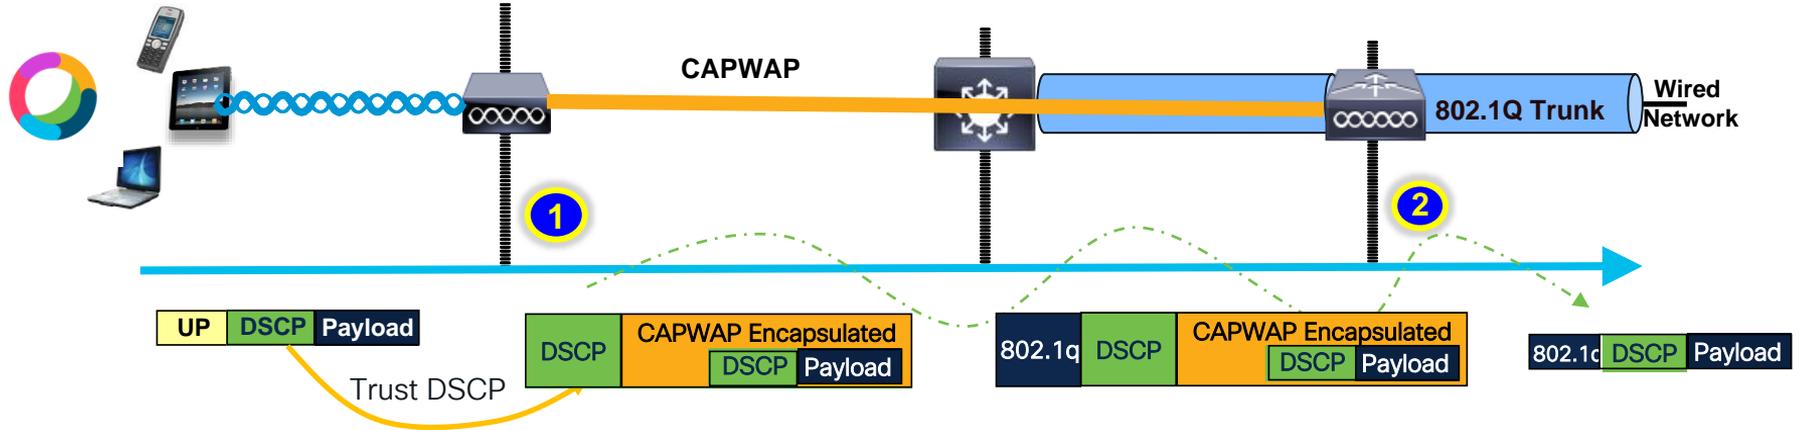

- 1** The client packet is received over an 802.1q trunk by the WLC. The WLC uses the DSCP value of the original IP packet and maps it to the outer DSCP of the CAPWAP tunnel (assuming no ceiling value is applied via Metal QoS at the WLC). It also maps DSCP to UP and set it in the inner 802.11e header
- 2** The AP leverages the inner UP value received from the WLC for internal QoS processing and queuing. The 802.11e UP value is also copied in the egress wireless 802.11 frame to the client, over the air

# Catalyst 9800 Upstream QoS Model

1

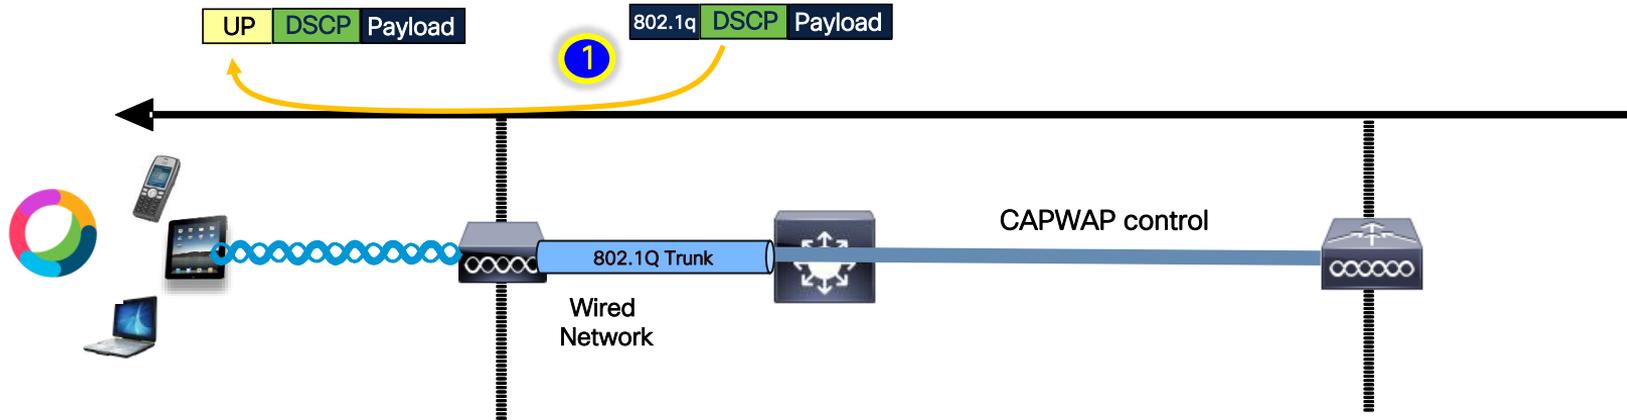

The client 802.11e frame is received by the AP. The AP utilizes the DSCP value in the original packet for internal QoS processing and then maps it to the outer CAPWAP IP header, (assuming no ceiling value is applied via Metal QoS at the WLC)(\*))

2

This allow preservation of the DSCP value from the client all the way through the network, emerging untouched from the WLC (assuming no Metal QoS or AVC policy is applied to remark DSCP)

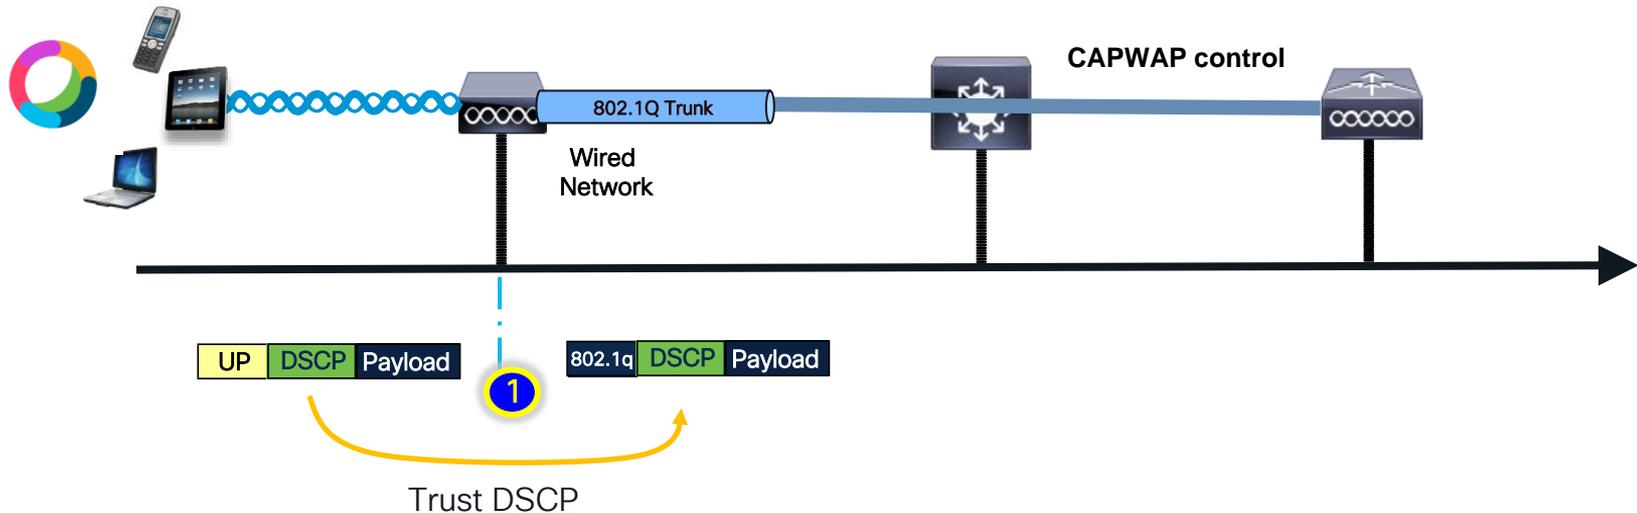

# Downstream QoS Variant: Flex Local Switching

- 1 Once the Ethernet frame is received, the AP takes the DSCP value of the IP packet, process any QoS policy (e.g., AVC policy), maps it to the 802.11e UP value on the wireless frame and queue the frame accordingly. The frame is then sent to the client.

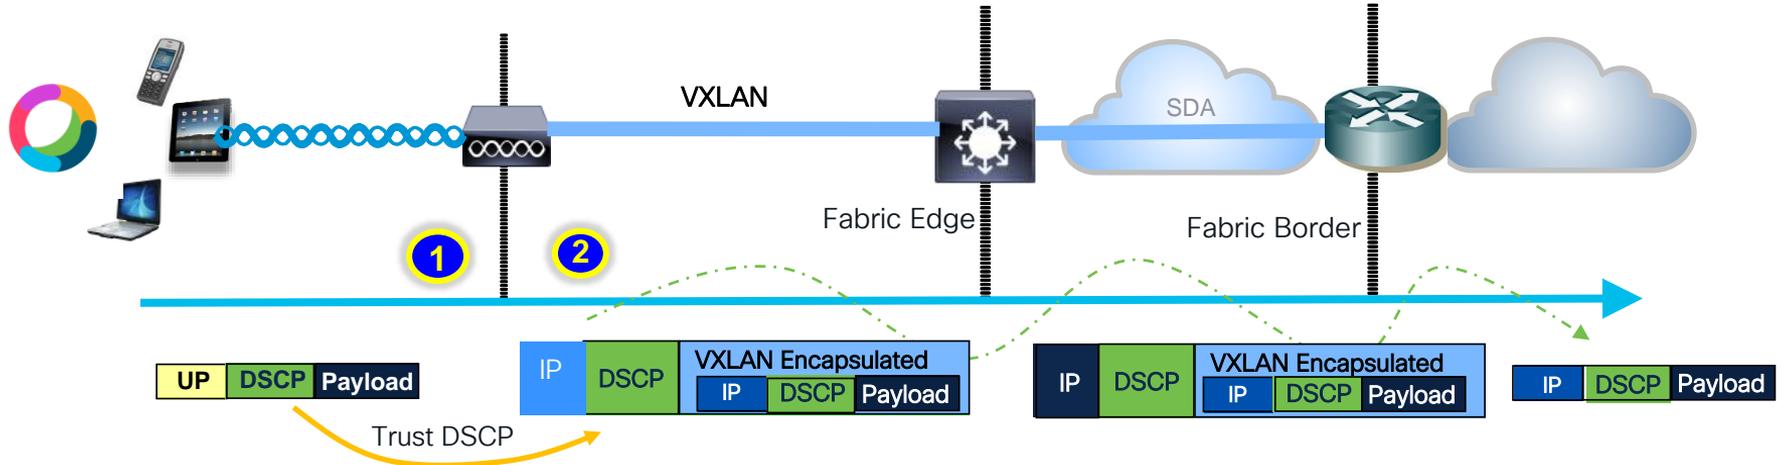

# Upstream QoS Variant: Flex Local Switching

- 1 The client 802.11e frame is received by the AP. The AP looks at the original packet DSCP to apply any QoS policy before sending the packet onto the wire

# Upstream QoS Variant 2: SDA Fabric

- 1 The client 802.11e frame is received by the AP. The AP utilizes the DSCP value in the original IP packet for internal QoS processing and then maps it to the outer VXLAN header(\*)
- 2 This allow preservation of the DSCP value from the client all the way through the network, emerging untouched from the Border (assuming no Metal QoS or AVC policy is applied to remark DSCP)

(\*) Before release 17.4, you need to explicitly configure “qos-map trust-dscp-upstream” under the AP join profile. If this setting is not there, the AP will use the UP value in the received frame to derive the outer DSCP value of the VXLAN header

# Under the Hood: Catalyst 9800 IOS-XE is Based on Modular QoS

- Catalyst QoS model is based on **Modular QoS CLI (MQC)**
- In IOS-XE, **MQC** is used to implement the Differentiated Service model QoS
- The main MQC constructs:
  - **Class-map:** to classify traffic
  - **Policy-map:** to bind traffic class to actions
  - **Service-policy:** to attach policy-map to target/direction

## Classification ACL

```
ip access-list extended AutoQos-4.0-Output-Acl-CAPWAP-C
10 permit udp any eq 5246 16666 any
```

## Class-map definition

```
class-map match-any AutoQos-4.0-Output-CAPWAP-C-Class
match access-group name AutoQos-4.0-Output-Acl-CAPWAP-C
class-map match-any AutoQos-4.0-Output-Voice-Class
match dscp ef
```

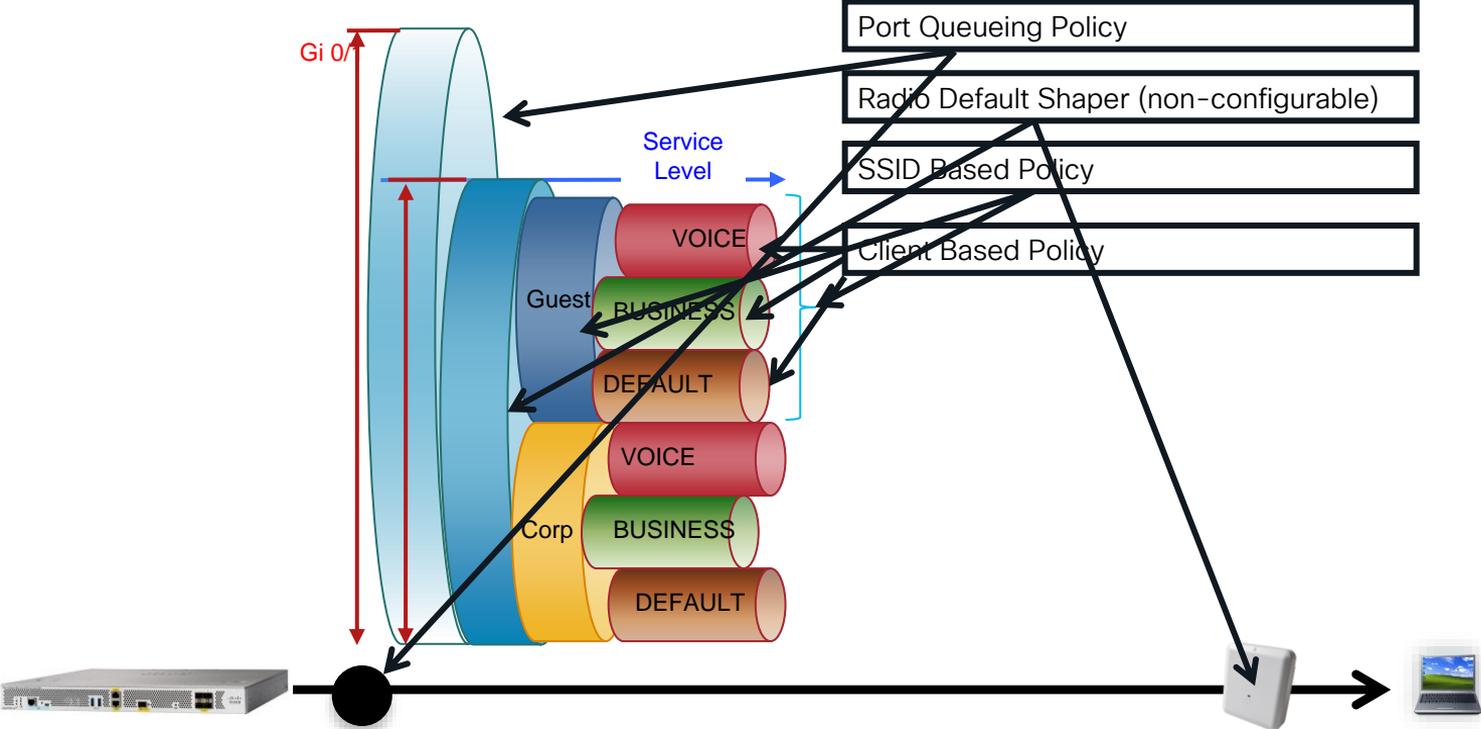

## Policy-map definition

```
policy-map AutoQos-4.0-wlan-Port-Output-Policy
class AutoQos-4.0-Output-CAPWAP-C-Class
priority level 1
class AutoQos-4.0-Output-Voice-Class
priority level 2
class class-default
```

## Service-policy attachment

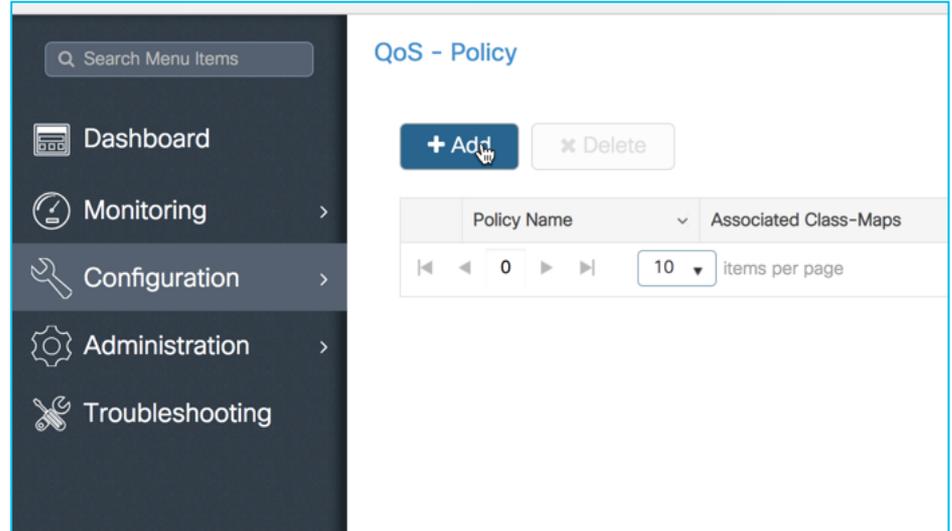

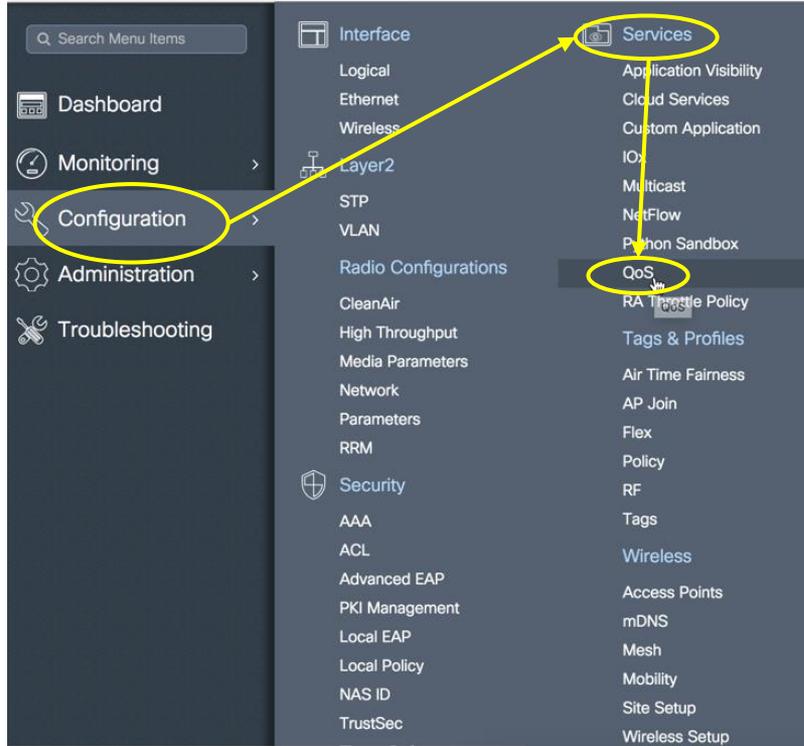

```
interface TenGigabitEthernet0/0/0
service-policy output AutoQos-4.0-wlan-Port-Output-Policy
```

# Controller Hierarchical Wireless QoS

# Configuring QoS on the Catalyst 9800 Controller

Begin by Navigating to Services > QoS and Add a new policy

# QoS Policy Workflow

Name your policy, add applications (Class-maps)

The screenshot displays the 'Add QoS' configuration window. On the left is a dark sidebar with navigation options: Dashboard, Monitoring, Configuration, Administration, and Troubleshooting. The main area is titled 'Add QoS' and contains the following elements:

- Auto QoS:** A toggle switch currently set to 'DISABLED'.
- Policy Name\*:** A text input field containing 'MyPolicy', which is circled in blue.
- Description:** An empty text input field.
- Table:** A table with columns: Match Type, Match Value, Mark Type, Mark Value, Police Value (kbps), Drop, AVC/User Defined, and Actions. Below the table is a pagination control showing '0' items per page and 'No items to display'.
- Buttons:** A blue '+ Add Class-Maps' button and a grey 'Delete' button, both circled in blue.
- Class Default:** A section with 'Mark' set to 'None' and 'Police(kbps)' set to '8 - 10000000'.
- Profiles:** A section with a search bar and two columns: 'Available (1)' and 'Selected (0)'. Under 'Available (1)', there is a profile named 'default-policy-profile' with a right-pointing arrow.

# Making Things Easy with Auto QoS

- None
- Guest
- Enterprise
- Voice
- Fastlane

The image shows a sidebar menu with the following categories and items:

- Search Menu Items
- Dashboard
- Monitoring
- Configuration
- Administration
- Troubleshooting
- Interface
  - Logical
  - Ethernet
  - Wireless
  - Layer2
    - STP
    - VLAN
    - Radio Configurations
    - CleanAir
    - High Throughput
    - Media Parameters
    - Network
    - Parameters
    - RRM
  - Security
- Services
  - Application Visibility
  - Cloud Services
  - Custom Application
  - IOx
  - Multicast
  - NetFlow
  - Python Sandbox
  - QoS
  - RA Throttle Policy
  - Tags & Profiles
  - Air Time Fairness
  - AP Join
  - Flex
  - Policy**
  - RF

The screenshot shows the 'Add Policy Profile' configuration window with the following sections:

- General**
- Access Policies**: A dropdown menu is set to 'None' and is circled in blue. A blue arrow points from the list in the top right to this dropdown.
- QoS and AVC** (Active Tab)
  - Auto QoS**: None
  - QoS SSID Policy**
    - Egress: platinum
    - Ingress: Search or Select
  - QoS Client Policy**
    - Egress: MyPolicy
    - Ingress: MyPolicy
- Mobility**
  - Flow Monitor IPv4**
    - Egress: Search or Select
    - Ingress: Search or Select
  - Flow Monitor IPv6**
    - Egress: Search or Select
    - Ingress: Search or Select
- Advanced**

Buttons at the bottom: Cancel, Save & Apply to Device

# Catalyst 9800 Auto QoS – explained

- **Voice:** sets the recommended QoS policy to correctly mark and prioritize voice at the SSID level and enables CAC.
- **Guest:** sets the recommended QoS policy at SSID level to mark everything to Best Effort
- **Enterprise:** sets the recommended QoS policy at SSID level to mark VoIP Data, and Signaling, Multimedia, Transaction, Bulk-Data and Scavenger traffic
- **Fastlane:** sets the specific EDCA parameters. Fastlane also sets clients specific policies only for Apple clients.
  - With All options queuing is configured on the C9800 egress port for prioritizing voice and CAPWAP traffic
  - Once Auto-QoS profile is applied on the policy profile, you can view the policies via the “**show policy map**” command and show the configuration via “show run”

# Remember this?

## AireOS Precious Metal QoS Method

The screenshot shows the Cisco AireOS configuration interface. The top navigation bar includes 'MONITOR', 'WLANs', 'CONTROLLER', 'WIRELESS', 'SECURITY', and 'MANAGEMENT'. The 'WIRELESS' tab is selected. On the left, a sidebar menu lists various configuration options under 'Wireless', with 'QoS' expanded to show 'Profiles' and 'Roles'. The main content area displays a table of QoS Profiles:

Profile Name	Description
<a href="#">bronze</a>	For Background
<a href="#">gold</a>	For Video Applications
<a href="#">platinum</a>	For Voice Applications
<a href="#">silver</a>	For Best Effort

Below the table, a vertical stack of four boxes contains DSCP values: DSCP 10, DSCP 34, DSCP 46, and DSCP 0. Arrows point from these boxes to the 'bronze', 'gold', 'platinum', and 'silver' profile names in the table above, respectively.

- The main purpose of the QoS profile is to limit the maximum DSCP allowed on a CAPWAP tunnel, and thus limit the 802.11 UP value
- QoS profiles may be used and applied to each WLAN (SSID)

# Catalyst 9800 – Improving Metal QoS Profiles

- QoS Metal Profiles in C9800:
  - For C9800 you can apply Metal QoS on Egress and Ingress direction separately
  - On the GUI, you can only set the Metal QoS per SSID. On CLI you can also configure it on client target
  - For each profile, a max DCSP setting is used to remark any traffic in excess of the DSCP limit

Qos Profile	Max DSCP
Bronze	8
Silver	0
Gold	34
Platinum	46

The screenshot shows the 'Edit Policy Profile' configuration page with the 'QoS and AVC' tab selected. The 'Auto QoS' dropdown is set to 'None'. Under 'QoS SSID Policy', the 'Egress' direction is set to 'platinum' and the 'Ingress' direction is set to 'platinum'. Under 'QoS Client Policy', the 'Egress' direction is set to 'Search or Select' and the 'Ingress' direction is also set to 'Search or Select'. A dropdown menu is open for the 'Ingress' QoS SSID Policy, showing a list of profiles: 'MyPolicy', 'platinum', 'gold', 'silver', and 'bronze', with 'platinum' selected.

# AVC QoS Workflow

Add applications and assign a policy

# Cat 9800 Custom AVC Capabilities

Custom apps and attributes can be defined by the user

## Custom IP, Port, DSCP

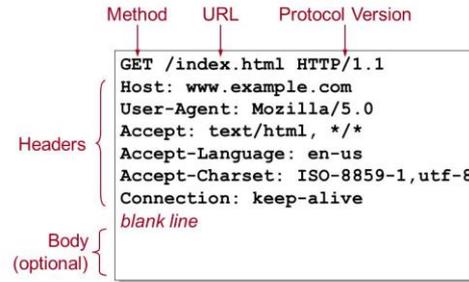

```
eWLC-AVC(config)#ip nbar custom customapp transport udp
eWLC-AVC(config-custom)#?
Custom protocol commands:
direction  Flow direction
dscp      DSCP in IPv4 and IPv6 packets
exit      Exit from custom configuration mode
ip        ip address
ipv6     ipv6 address
no       Negate a command or set its defaults
port     ports
```

Example:

```
C9800(config)#ip nbar custom my_app transport udp
C9800(config-custom)# ip address 9.9.71.50 9.9.71.11 9.9.71.14
C9800(config-custom)# port 1111
C9800(config-custom)# dscp 0
C9800(config-custom)# direction any
```

## Custom HTTP Host and URL

### HTTP Request

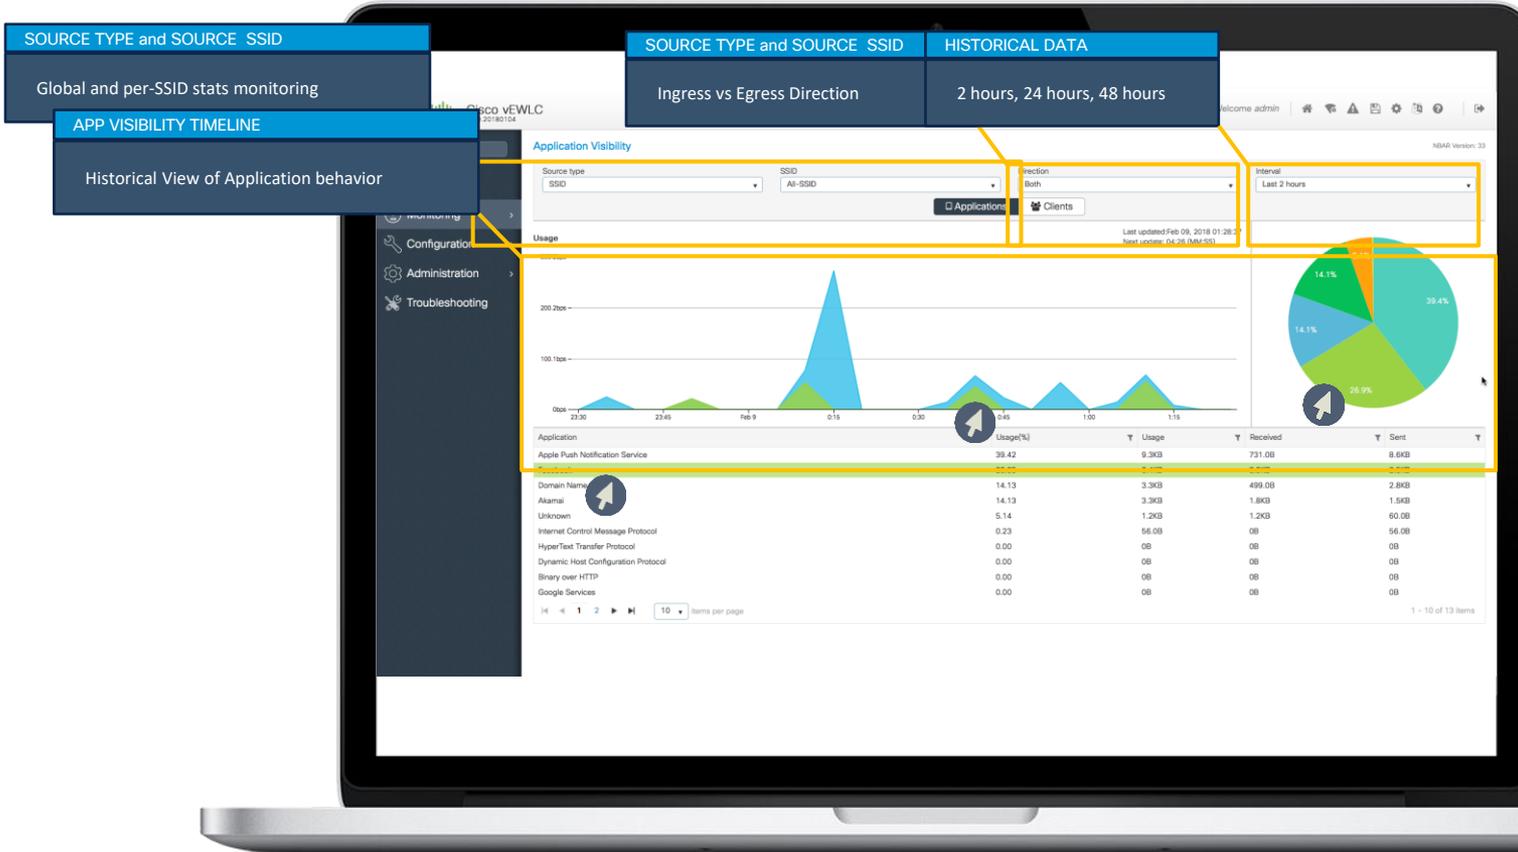

```
C9800(config)#ip nbar custom my_http http url "latest/whatsnew.html"
```

```
C9800(config)#ip nbar custom my_http http host "www.anydomain.com"
```

```
C9800(config)#ip nbar custom my_http http url "latest/whatsnew" host "www.anydomain.com"
```

The URL or host specification strings can take the form of a **regular expressions**

# Improved AVC Visualization and Reporting

# Looking to the Future: IEEE 802.11be and Beyond

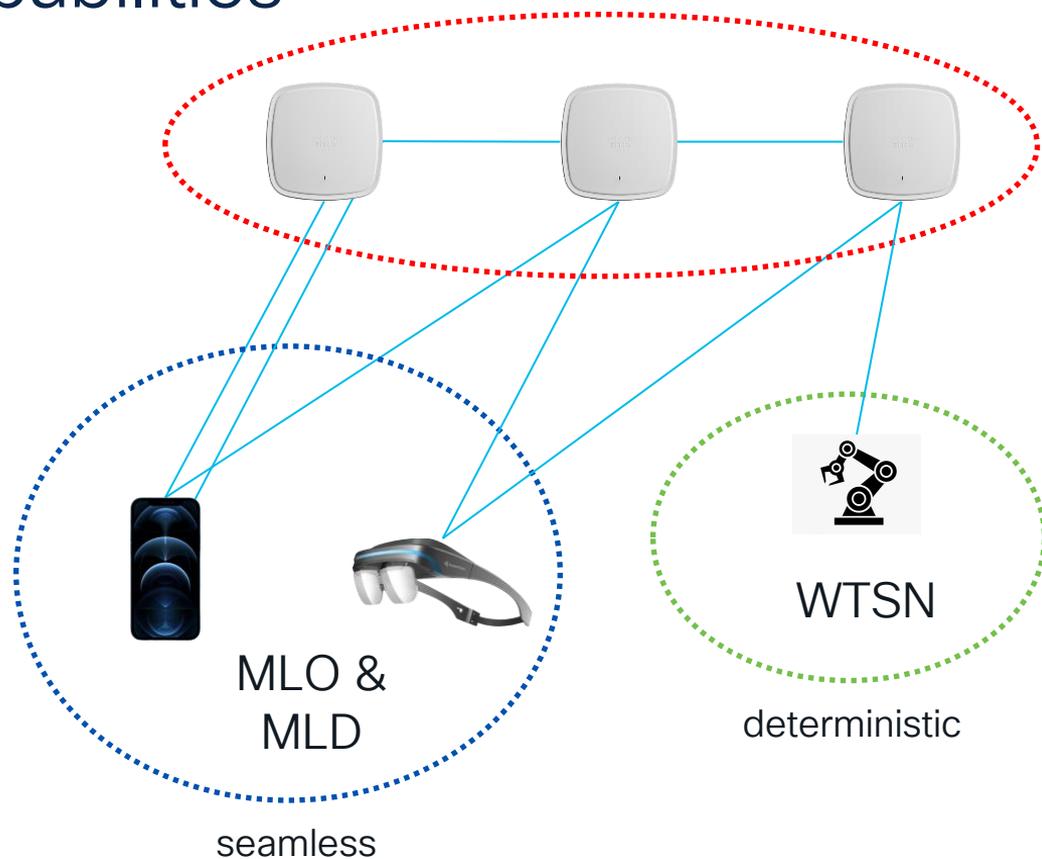

# Ultra Reliable and Deterministic Wireless

- 5G Release 16 introduced Ultra-Reliable Low Latency Communication (URLLC) for fast moving vehicles and seamless roaming
- Cisco CURWB (Fluidmesh) supports this today
- Wi-Fi will follow soon with 802.11be (Wi-Fi7)

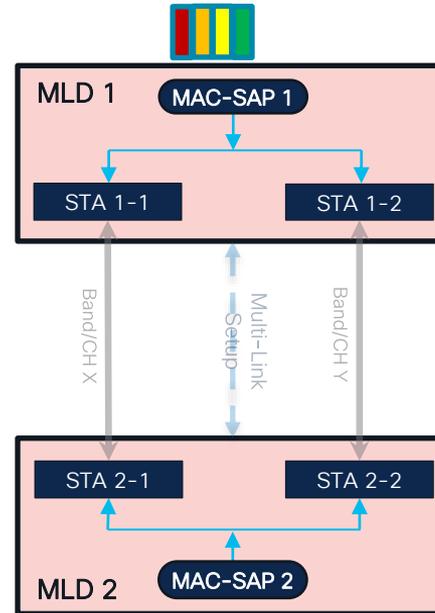

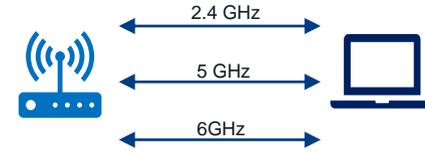

# IEEE 802.11be key capabilities

- Multi-Link Operations (MLO)
  - Ability to Tx and Rx on multiple channels
  - QoS-based link selection/steering
- MAPC
  - Time and space scheduling across multiple APs
- Wireless Time Sensitive Networking (TSN)
- Enhanced QoS Capabilities
  - SLA-based KPI delivery (latency, jitter, etc.)
  - Network and client-side support

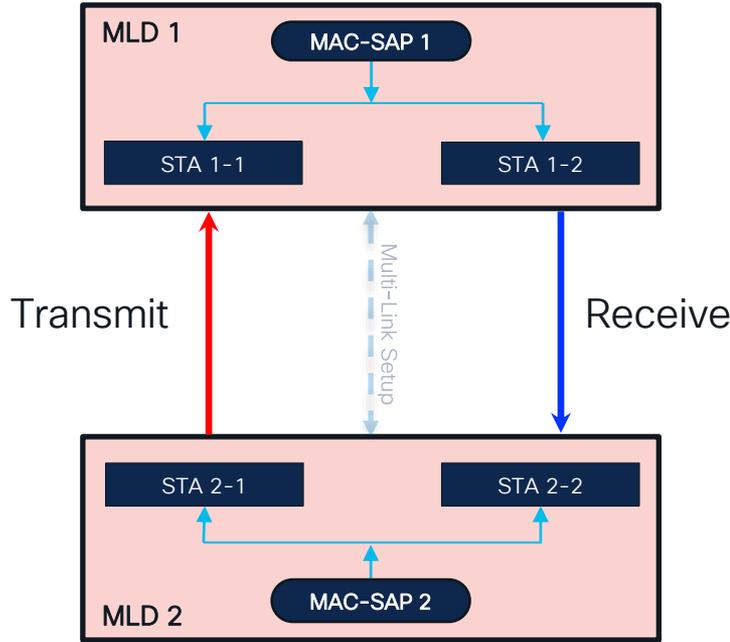

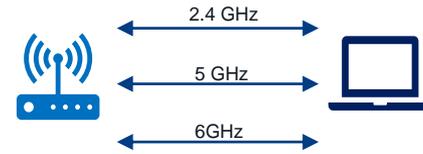

# Multi-Link Operation (MLO)

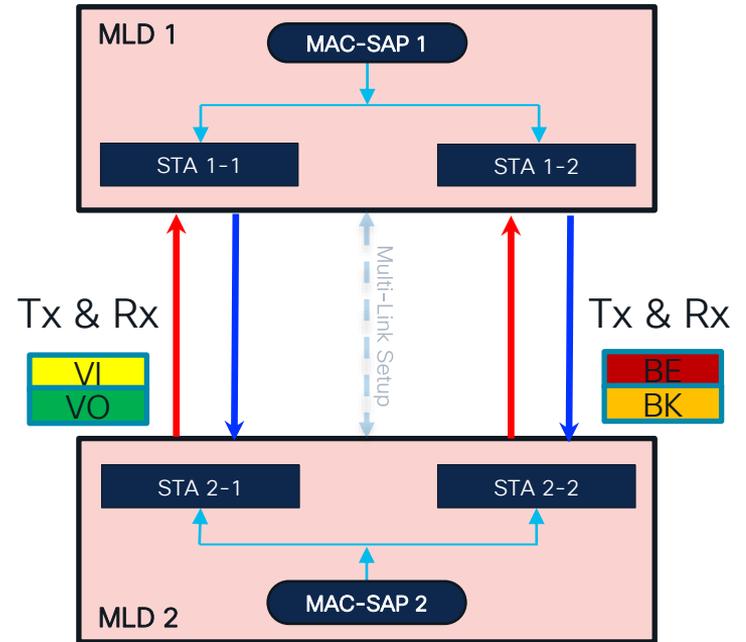

- A **MLO-capable** device is called a Multi-Link Device (MLD)
- The MLD can be associated to both/all radios of an AP using both or all of its radios
- MLDs have more than one affiliated Stations (STAs), but generally **ONE** MAC Service Access Point (SAP) connected to the LLC
- The SAP is tasked with aggregating data from multiple links

# Multi-Link Operation (MLO) Enables new Capabilities

STR Mode (Simultaneous Tx and Rx)  
Essentially Full-Duplex

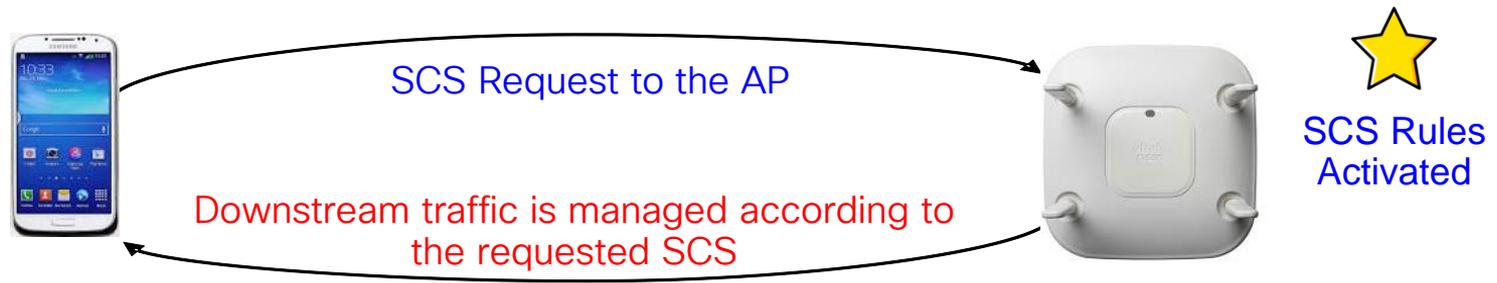

NSTR Mode (Non-Simultaneous Tx and Rx)  
Load balanced traffic across multiple links

Legend

# A New QoS Paradigm: 802.11aa Stream Classification Service (SCS)

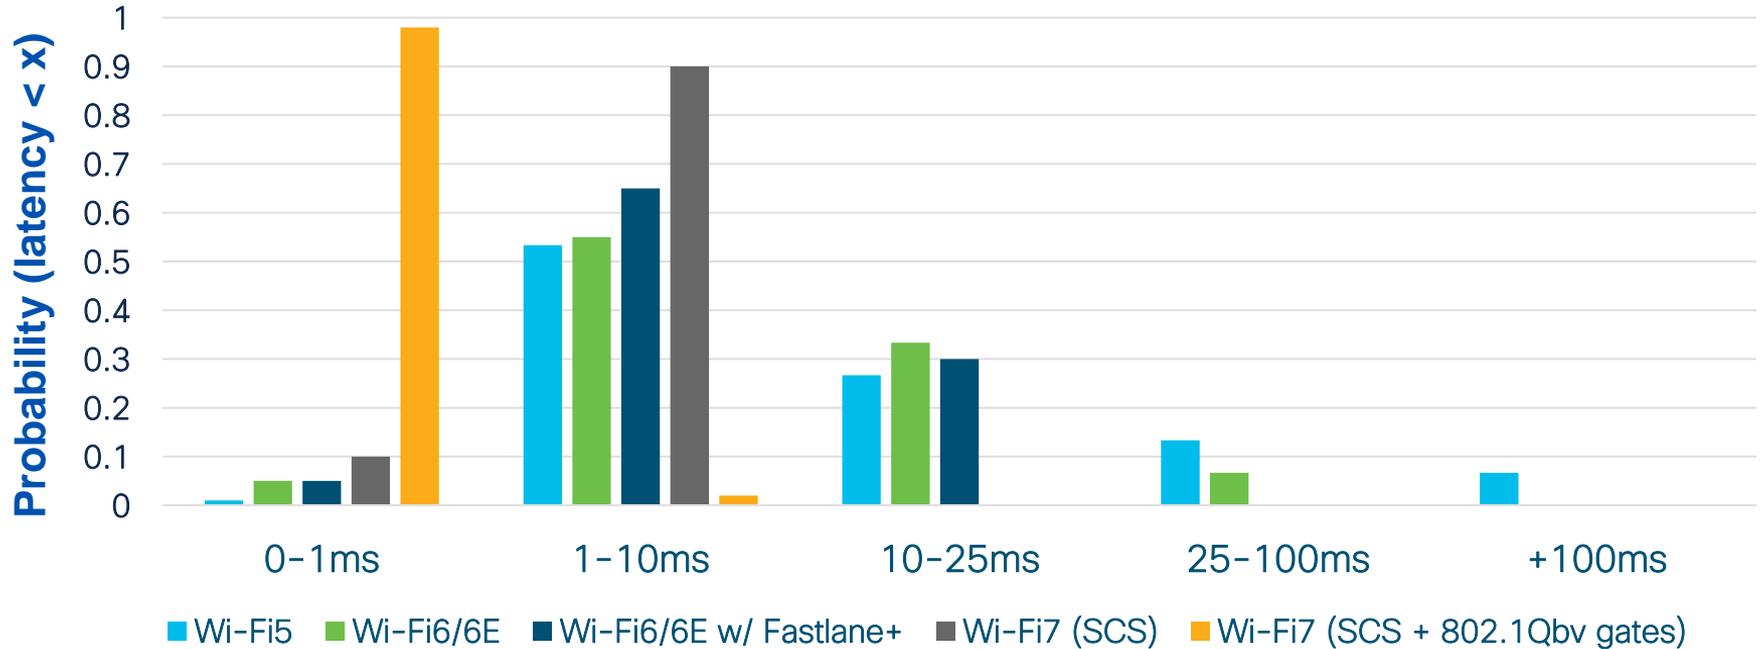

- SCS (Stream Classification Service) specifies traffic flows using an SCS request frame (a QoS **Information Element / IE**)
- The AP derives QoS rules by monitoring the corresponding uplink flows
- Allows the STA to explicitly provide traffic classifiers and priority for each downlink flow

# 802.11be / Wi-Fi7 QoS

- Traffic Identifiers (TIDs)
  - **TIDs** are a 4-bit QoS field in 802.11 header (the first 3 bits are where the UP value comes from) which are communicated in the SCS request
  - With 802.11be TIDs may be used to select optimal links (5GHz vs. 6GHz, etc.) – TID to radio link mapping
    - E.g. “Let’s send all low-latency HD video on 6GHz, but everything else on 5GHz”
- The SCS QoS IE specifies **traffic characteristics & requirements**
  - Inter-arrival-time / periodicity (max/min scheduling interval)
  - Delay, reliability (delivery ratio) & jitter (indirectly) requirements
  - Burst characteristics (size and window)
  - Exact alignment (e.g. TSN 802.1Qbv) via service-start-time (SST)

# Enhanced QoS: 802.11be SCS Enables Determinism

Latency performance improvements in high-traffic scenarios

Source: <https://mentor.ieee.org/802.11/dcn/22/11-22-0634-00-00be-802-11be-enhancements-for-tsn-time-aware-scheduling-and-network-management-considerations.pptx>

# Summary

# Conclusions

- Understanding the function of wireless QoS is foundational to any good deployment – especially the differences between EDCA and Wi-Fi6
- Think about how you will adapt a multi-class policy to wireless, which has only 4 classes
- Be aware of how Wi-Fi handles QoS mappings and markings, end-to-end
- IOS-XE improves on capabilities of AireOS, including the precious metal QoS model, extending AVC flexibility, and much more
- 802.11be QoS Innovations are coming in Wi-Fi to support new use cases

# Fill out your session surveys!

Attendees who fill out a minimum of four session surveys and the overall event survey will get **Cisco Live-branded socks** (while supplies last)!

Attendees will also earn 100 points in the **Cisco Live Challenge** for every survey completed.

These points help you get on the leaderboard and increase your chances of winning daily and grand prizes
